ABSTRACT

Varicoceles are the abnormal tortuosity and dilatation of the veins of the pampiniform plexus that drain the testis. Varicoceles are variously considered the commonest “correctable” cause of infertility or the commonest “reported” cause of infertility depending on individual viewpoint. Even though the pathophysiology of testicular damage in varicocele has not been completely understood, there is an increasing body of evidence pointing towards the role of reactive oxygen species (ROS) and oxidative stress in the pathogenesis of varicocele related subfertility. In this study we investigated the role of L-ascorbate (vitamin C) as an antioxidant in rejuvenating the testis following its damage in experimental varicocele. Thirty male Sprague-Dawley weighing 150-200 g were divided into three groups. While the first group had sham operations, experimental varicoceles were established by complete ligation of the left and right main spermatic vein in the later two groups. The third group in addition to varicocele induction had daily gavage administration of 8 mg kg$^{-1}$ body weight vitamin C for fifty six days. All animals were sacrificed by decapitation fifty six days after varicocele induction. Testicular weights, testicular volumes, caudal epididymal sperm characteristics, testicular histology and serum hormone levels were evaluated. Results showed that the testes of the rats that were given vitamin C post experimental varicocele had better physiological, biochemical and histological profiles than those of the untreated animals. These results indicate the potency of vitamin C for modulating testicular toxicity in varicocelezed animals.

Key words: Varicocele, ascorbic acid, testis, infertility.

Introduction

Varicocele, the abnormal tortuosity of the veins of the pampiniform plexus that drain the testis is one of the main causes of male infertility. In a World Health Organization multicentre study on 9043 infertile couples, varicocele was found in 25.4% of men with abnormal semen, compared with 11.7% of normal semen [20]. It was shown that the presence of grade I varicocele in adolescence appears to have no effect on normal testicular growth, but patients with grade II varicocele are at risk of unilateral testicular volume loss and grade III varicocele, of bilateral testicular volume loss [5]. However the pathogenesis of testicular damage or the mechanism of which varicocele produces sperm dysfunction has not been clearly identified yet [13]. The proposed mechanisms include testicular hypoxia by venous stasis and small vessel occlusion, leading to Leydig cell and germinal cell dysfunction, increased testicular and scrotal temperature and decrease in gonadotrophin and androgen secretion [4]. Irrespective of the infertility status, it was identified that there is a strong relationship between sperm

dysfunction and varicocele [6,2]. Varicocele is associated with increased production of spermatozoal Reactive oxygen species (ROS). Indeed, Hendin et al. [2] reported a 4-fold increase in the frequency of elevated ROS generation in the incidental varicocele group compared to their control patients. ROS are species such as superoxide, hydrogen peroxide, and hydroxyl radical and are associated with cell damage. A characteristic feature of most, if not all, biological membranes is an asymmetrical arrangement of lipids within the bilayer. The lipid composition of plasma membrane of mammalian spermatozoa is markedly different from those of mammalian somatic cells. They have very high levels of phospholipids, sterols, saturated and polyunsaturated fatty acids. Therefore sperm cells are particularly susceptible to the damage induced by Reactive Oxygen Species (ROS) release [2]. ROS are cytotoxic and cause tissue injury in several pathophysiology, such as cancer, glomerular nephritis and arthritis. Thus sperm dysfunction may be a consequence of elevated seminal ROS. Several studies have also demonstrated that in the presence of increased antioxidant enzyme levels, testicular dysfunction can be prevented in varicoceleized subjects [2,18,16].

Treatments involving antioxidants have been used successfully to decrease oxidative stress related injuries in many organ systems as well as in the testis [18,911].

L-ascorbate (Vitamin C) is an essential nutrient for a large number of higher primate species, a small number of other mammalian species (notably guinea pigs and bats), a few species of birds, and some fish [7]. The pharmacophore of vitamin C is the ascorbate ion. In living organisms, ascorbate is an antioxidant, since it protects the body against oxidative stress [10].

Although varicocelectomy is considered as a highly effective treatment of infertility due to varicoceles, a significant number of men remain infertile after varicocelectomy [17]. Therefore there is an increasing interest to develop conservative modes of therapy of infertility due to varicoceles. Considering that Oxygen radical scavengers provide significant restoration of testicular function after testicular vascular diseases [3,12], we aim to study the effect of the administration of Vitamin C on testicular morphology, and testicular spermatogenic and steroidogenic functions in rats that had earlier been varicoceleized.

Materials and methods

The drug

Ascorbate was obtained at Julie Pharmacy Ikeja, Lagos.
Estimation of plasma levels of testosterone

Plasma testosterone concentrations were estimated using the Enzyme Immunology Assay (EIA) method as earlier described [11]. Plasma samples were collected were stored at – 20°C while assayed. The EIA kits used were obtained from Immunometrics (London U. K) and contained testosterone EIA substrate reagents and EIA quality control samples. A quality control sample was run for the hormone at the beginning and at the end of the assay variation. The EIA kit used had a sensitivity level of 0.3 nmol L⁻¹ (0.1 ng mL⁻¹). The intra and inter assay variations were 11.00 and 10.10% respectively.

Histological Analysis

This was done as essentially as described by Akpanlah et al. The organs were cut in slabs of about 0.5 cm thick and fixed in Bouin’s fluid for a day after which it was transferred to 70% alcohol for dehydration. The tissues were passed through 90% alcohol and chloroform for different durations before they were transferred into two changes of molten paraffin wax for 20 min each in an oven at 57°C. Serial sections of 5 µm thick were obtained from a solid block of tissue and were stained with haematoxylin and eosin stains, after which they were passed through a mixture of equal concentration of xylene and alcohol. Following clearance in xylene, the tissues were oven-dried. Light microscopy was used for the evaluations.

Statistical Analysis

Data were expressed as mean ± SEM. They were subjected to analysis of variance (ANOVA). Statistical significance between the various groups was separated by t – test (SAS, 2002).

Results and discussion

Body Weight Changes

Table 1 shows that rats in control group had significant (P<0.05) increase in weight. Both varicocelezed groups lost weights when compared with their initial weights. However the weight loss by the varicocelezed rats that received vitamin C was less than the losses by varicocelezed group that did not receive vitamin C.

Weights and Volume of testes mean

Table 1 also shows that the testicular weights and volumes of the varicocelezed alone were the least, being significantly lower (P<0.05) compared to the mean testicular weights and volumes of the varicocelezed rats that in addition had vitamin C.

Epididymal Sperm Characteristics

Spermatozoa concentration:

As shown in Table 2, the varicocelezed alone group had marked oligospermia with their sperm concentration being significantly lower (P<0.01) compared to the control group. The varicocelezed with vitamin C group however showed only moderate oligospermia, the sperm concentration being significantly lower (P<0.05) than the control group.

Spermatozoa motility

Even though percentage sperm motility of both the varicocelezed alone and varicocelezed with vitamin C groups were significantly lower (P<0.01 and P<0.05 respectively) compared to the control group, the varicocelezed with vitamin C group still had a significantly higher (P<0.05) sperm motility than the varicocelezed alone group (Table 2).

Progressivity of spermatozoa motility

The sperm cells from the cauda epididymides of both varicocelezed alone and varicocelezed with vitamin C groups showed sluggish linear or non-linear movement. Spermatozoa from the control group exhibited progressive rapid linear movement.

Serum Testosterone Levels

There was a significantly lower (p<0.05) serum testosterone levels in the varicocelezed alone rats compared with the control rats. The serum testosterone level of the varicocelezed rats that were post treated with vitamin C was lower but not significantly lower (p>0.5) when compared to the control. (Figure 1).

Testis Morphology

Light microscopy was used for evaluation of testicular histology as shown in plates 1-3. The seminiferous tubules of the control rats were completely differentiated. Spermatozoa are shown in some of the tubules. However in the varicocelezed group without vitamin C treatment there was marked degeneration of the seminiferous tubules. There was also widening of the lumen as a result of hypospematozoa formation. The testes of the rats that had vitamin C following varicocele induction showed fairly preserved seminiferous tubules and stroma architecture.

Discussion

The results from the present study showed a derangement of the growth and reproductive functions of the animals. The gain in live body weight of the control rats meant that the rats were still in the active growth phase. The loss in live body weight of the experimental groups indicates that artificial varicocele has a negative effect on the body metabolic process. The procedure for achieving artificial varicocele confers a conspicuous level of stress on the rats. This stress could affect their metabolic process leading to losses in live weights observed in this study.

The lower testes weights in varicocele compared to the control corroborate the report of Suzuki and Sofikitis [17]. Semercioz et al. [15], also reported degenerative changes in the seminiferous epithelium of testes that were made varicocele, due to the effects of heat from venous stasis on the spermatogenic cells within the epithelium leading to loss in testicular weight. The findings of largely normalized testicular weights in animals that had vitamin C following experimental varicocele indicate a protective role.

Varicocele which is a leading cause of male infertility is associated with increased production of spermatozoal ROS. Irrespective of the infertility status, it was identified that there is a strong relationship between sperm dysfunction and varicocele [6,2]. Indeed Hendin et al. [2], reported a 4-fold increase in the frequency of elevated ROS generation in the incidental varicocele group compared to their control patients.

The results from our present study showed a moderate oligospermia (23.25 ± 5.07 × 10^6 mL^{-1}) in the varicocelezed rats that had vitamin C. This is a significant improvement over the marked oligospermia (1.34 ± 4.80 × 10^6 mL^{-1}) observed in varicocelezed rats that were not given vitamin C. This confirms the moderating effect of vitamin C as a potent antioxidant and a free radical scavenger [1]. Furthermore, treatment with vitamin C improved bilateral testicular functions and helped the epididymal sperm maturation process as indicated by the significantly higher cauda epididymal sperm motility. Administration of vitamin C may support the natural antioxidant mechanism of testicular tissue and partly protects the tissue damage due to induction of varicocele. However it should be noted that despite proven benefits of vitamin C administration, the values of qualitative and quantitative sperm parameters remain significantly lower than those of the control group.

The ameliorating effects of vitamin C are further demonstrated by the significant improvement in the histological profiles of varicocelezed with vitamin C group when compared to the testicular morphology of the varicocelezed alone group. As shown in our results varicocele brought about a significant reduction in the serum testosterone levels. This indicates a gross derangement of the Leydig cells since delicate alterations in Leydig cell secretory function may not be accompanied by alterations in peripheral serum androgen levels [14].

It is noteworthy however that there was no significant decline in the serum levels of testosterone in the varicocelezed with vitamin C group when compared to the control. This provides the evidence that the rejuvenating role of vitamin C in varicocelezed testis is both on the spermatogenic and steroidogenic functions.

Conclusion

In conclusion, our study showed a protective effect of vitamin C on testicular histology and physiology. Although varicocelectomy is considered as a highly effective treatment of infertility due to varicoceles, a significant number of men remain infertile after varicocelectomy. The possibility of vitamin C supplementation in this subset of infertile men could be considered.
